

David Khachatryan - Week 8 Report

Summary

This week, we successfully completed the camera integration and autonomous yaw milestones in approximately 45 minutes. Although the controlled flight milestone presented significant challenges due to unexpected pitch issues caused by the battery shifting forward, we identified the root cause and made temporary improvements using rubber bands. However, the recurring issue impacted our overall progress. Moving forward, I plan to enhance my flying skills to ensure I can reliably achieve controlled flight, enabling us to proceed smoothly with upcoming milestones.

What went well

We had about 45 minutes to spend on the camera and autonomous yaw milestones. We quickly finished the camera integration and got the autonomous yaw working a little bit after class was over. Despite our controlled flight milestone not going so well, we managed to quickly get started on the final set of milestones.

What did not go well, why?

For the controlled flight milestone, we had an issue with the robot's pitch. After increasing the thrust, within a few seconds the robot would pitch down without any input. Our controller was unchanged, so this was confusing. We further inspected the drone and it looks like the battery had slid forward slightly, which altered the drone's dynamics. We tried fixing the battery with rubber bands and that improved the flight, but this issue kept happening, which put a damper on our progress and the ability to move to the next milestones.

What will you change for next class

My flying skills were not so great. Before next class, it would be helpful for me to make sure that I passed the controlled flight milestone to ensure that we are able to move on further.

Contributions

The controlled flight milestone was only achieved by Burke this week. Since I was unable to finish this, it held us back, so Burke did about 60 and I did 40.
